POST CRYOTHERAPY

We are using cryotherapy (liquid nitrogen spray) to treat the following type of lesion(s):

1. You may experience a burning sensation that should subside after a short period of time. You may take an over-the-counter pain reliever if desired.
2. You may form a blister. This may be covered with a bandaid.
3. You will form a scab. These may be ignored or covered with a bandaid at your convenience. Do not pick the scab as that may cause scarring. If the scab is completely dry, it may be covered with make-up.
4. The lesion will come off in 2-3 weeks and there will be a red, white or brown area of new skin underneath. The length of time it takes for this area to become less noticeable is quite variable.
5. Protect the area from the sun for at least a year. Apply sun screen and/or cover the area. New skin is more sensitive to the sun and permanent pigment changes can occur with sun exposure.
